# Outline

- (Stochastic) System Models
- Linear Systems and Gaussian Noise
- Kalman Filter
- Non-Linear Systems and Gaussian Noise
- Extended Kalman Filter

# System Model

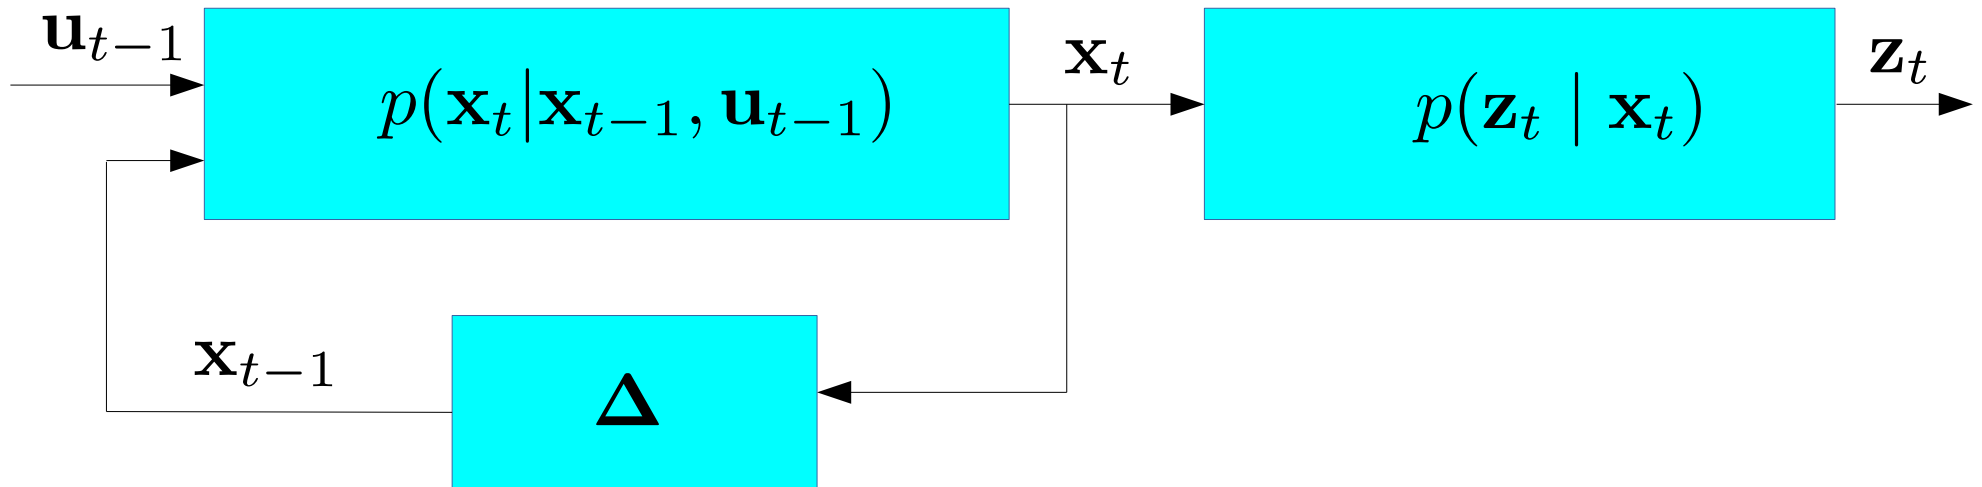

## Notation:

- $\mathbf{u}$ : controls
- $\mathbf{x}$ : state
- $\mathbf{z}$ : measurement
- $\mathbf{f}$ : transition function
- $\mathbf{h}$ : observation function

## Perfect knowledge of

- inputs
- measurements
- transition model
- observation model

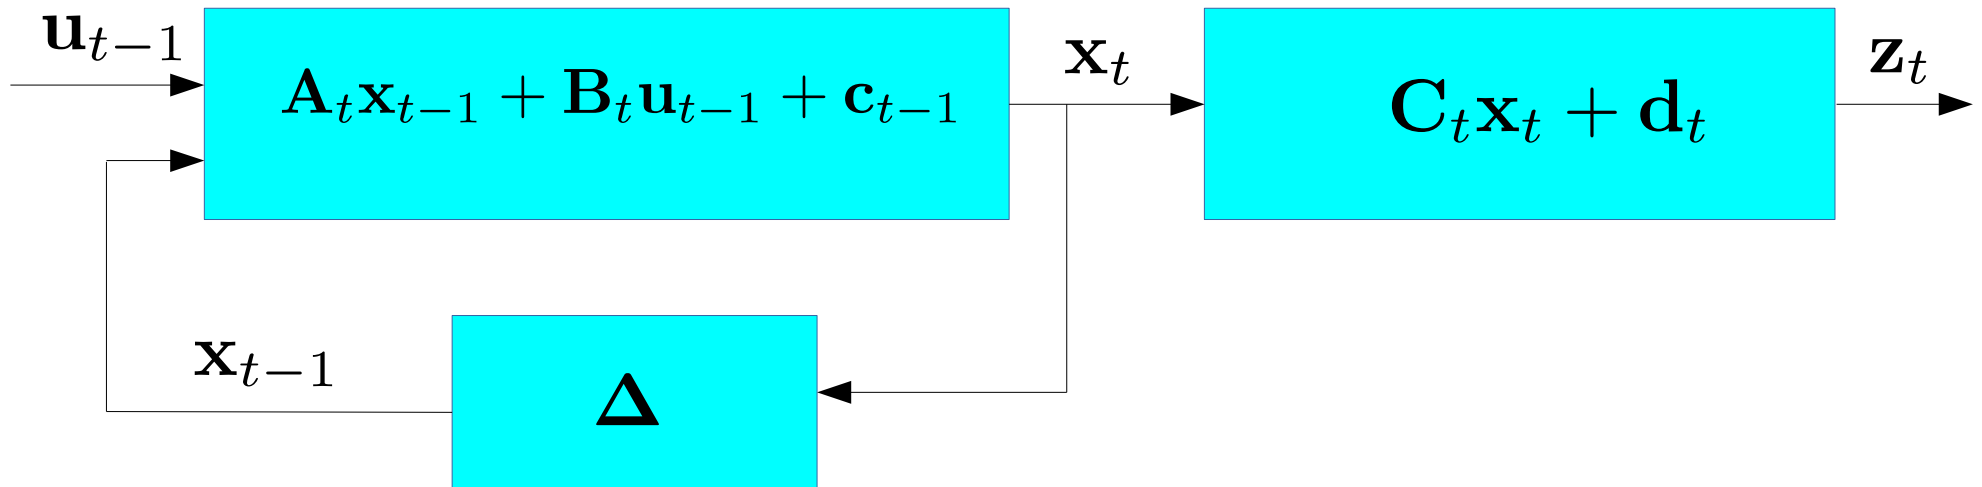

# Stochastic System Model

Transition and observation functions are replaced by conditional distributions

- Transition Model  $p(\mathbf{x}_t | \mathbf{x}_{t-1}, \mathbf{u}_{t-1})$
- Observation Model  $p(\mathbf{z}_t | \mathbf{x}_t)$

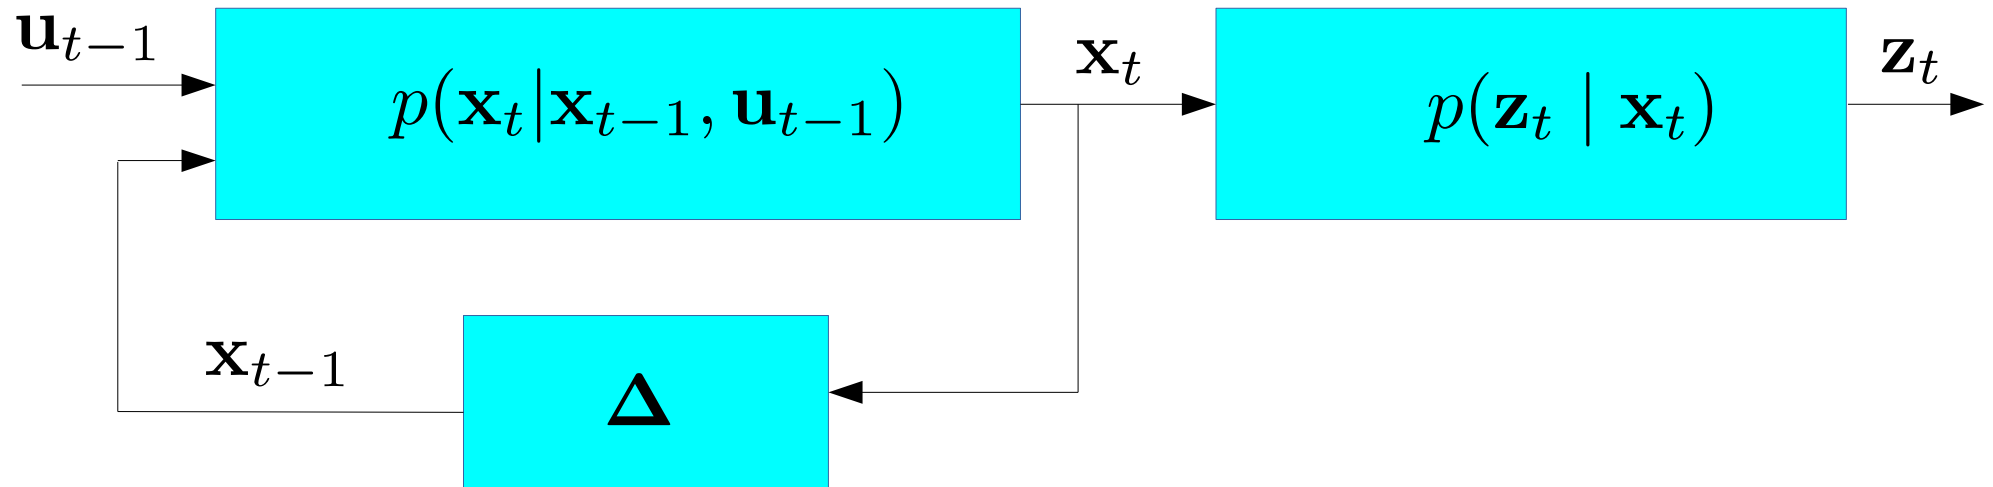

# Linear System

Transition and observation functions are affine transforms

- **A**: state transition matrix
- **B**: input matrix
- **C**: observation matrix

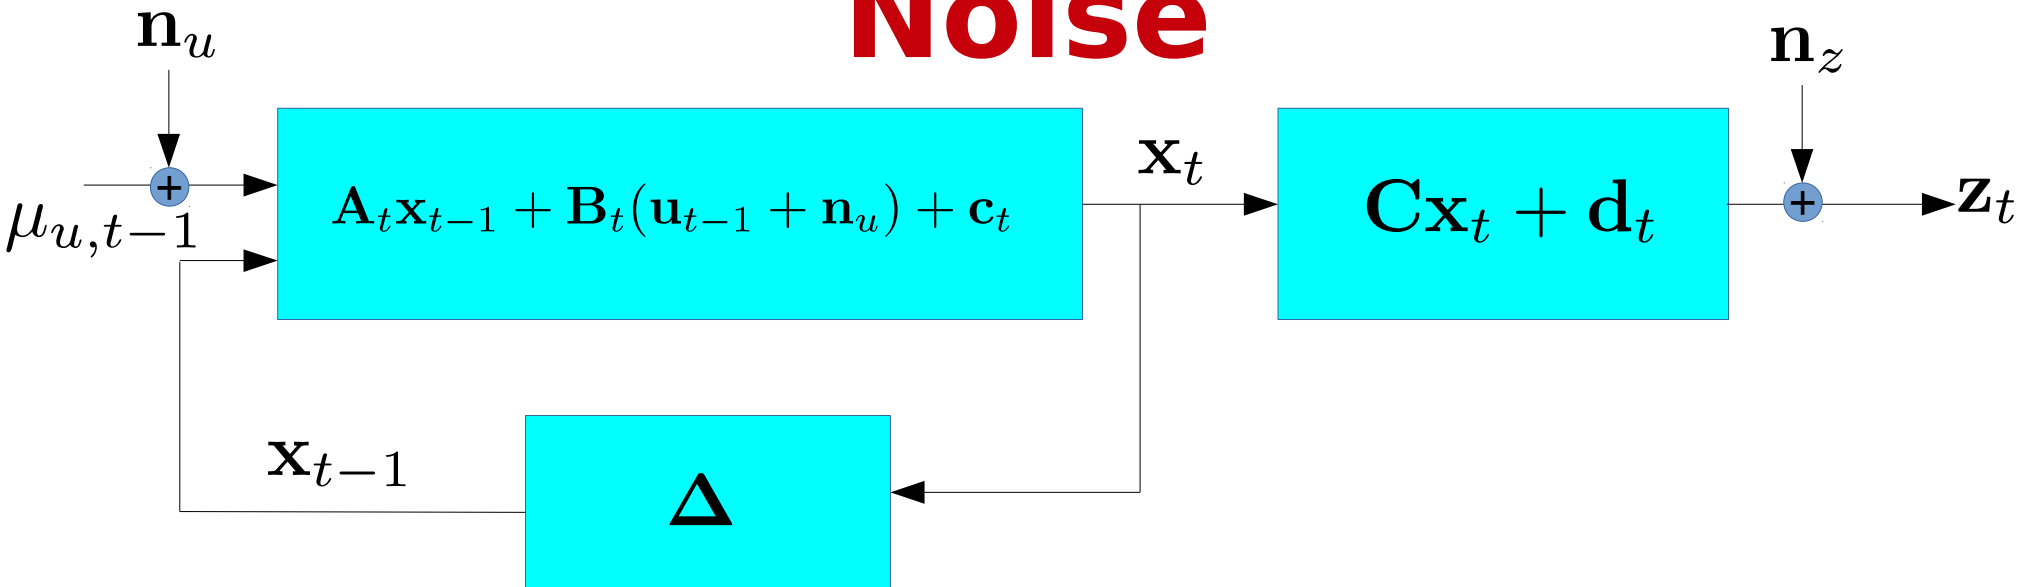

# Linear System with Gaussian Noise

Transition and observation functions are replaced by conditional distributions

- $p(\mathbf{x}_t | \mathbf{x}_{t-1}, \mathbf{u}_{t-1}) = \mathcal{N}(\mathbf{x}_t; \mathbf{A}\mathbf{x}_{t-1} + \mathbf{B}\mathbf{u}_{t-1} + \mathbf{c}, \Sigma_x)$
- $p(\mathbf{z}_t | \mathbf{x}_t) = \mathcal{N}(\mathbf{z}_t; \mathbf{C}\mathbf{x}_t + \mathbf{d}_t, \Sigma_z)$

# Linear System with Gaussian Noise

Inputs and Observations are affected by zero mean Gaussian noise. Initial belief is Gaussian

$$\mathbf{n}_u \sim \mathcal{N}(\mathbf{n}_u | 0, \Sigma_u)$$

$$\mathbf{n}_z \sim \mathcal{N}(\mathbf{n}_z | 0, \Sigma_z)$$

For compactness we embed the noise in the control

$$\mathbf{u}_{t-1} \sim \mathcal{N}(\mathbf{u}_{t-1} | \mu_{u,t-1}, \Sigma_{u,t})$$

# Filtering

## Some considerations

- The initial belief is Gaussian
- The noise is Gaussian
- All functions are affine

## Gaussian distributions are closed under

- Affine transformation
- Chain rule
- Marginalization
- Conditioning

**The belief remains Gaussian**

# Predict

Incorporate the control by computing the Gaussian distribution of the next state given the input

The next state is an affine transform of the past state and the controls:

$$\mathbf{x}_t = \begin{pmatrix} \mathbf{A}_t & \mathbf{B}_t \end{pmatrix} \begin{pmatrix} \mathbf{x}_{t-1} \\ \mathbf{u}_{t-1} \end{pmatrix} + \mathbf{c}_t$$

The previous states and controls are distributed according to:

$$\begin{pmatrix} \mathbf{x}_{t-1|t-1} \\ \mathbf{u}_{t-1} \end{pmatrix} \sim \mathcal{N} \left[ \begin{pmatrix} \mu_{t-1|t-1} \\ \mu_{u,t-1} \end{pmatrix}; \begin{pmatrix} \Sigma_{t-1|t-1} & \mathbf{0} \\ \mathbf{0} & \Sigma_{u,t-1} \end{pmatrix} \right]$$

# Affine Transformation

Let  $\mathbf{x}_a$  be a Gaussian random variable such that

$$\mathbf{x}_a \sim \mathcal{N}(\mathbf{x}_a; \mu_a, \Sigma_a)$$

Let  $\mathbf{x}_b = \mathbf{f}(\mathbf{x}_a) = \mathbf{A}\mathbf{x}_a + \mathbf{c}$   
an affine transformation of  $\mathbf{x}_a$

$\mathbf{x}_b$  is Gaussian:

$$p(\mathbf{x}_b) = \mathcal{N}(\mathbf{x}_b; \mu_b, \Sigma_b)$$

The parameters are

$$\mu_b = \mathbf{A}\mu_a + \mathbf{c} \quad \Sigma_b = \mathbf{A}\Sigma_a\mathbf{A}^T$$

# Predict

$$\begin{aligned}p(\mathbf{x}_{t|t-1}) &= \mathcal{N}(\mathbf{x}_{t|t-1}; \mu_{t|t-1}, \Sigma_{t|t-1}) \\ \mu_{t|t-1} &= \mathbf{A}_t \mu_{t-1|t-1} + \mathbf{B}_t \mu_{u,t-1} + \mathbf{c}_t \\ \Sigma_{t|t-1} &= \mathbf{A}_t \Sigma_{t-1|t-1} \mathbf{A}_t^T + \mathbf{B}_t \Sigma_u \mathbf{B}_t^T\end{aligned}$$

Apply the rule on the affine transformation

No need to marginalize, since this step is included in the transformation

# Update: Chain Rule

Given the following distributions

$$\begin{aligned}p(\mathbf{z}_t|\mathbf{x}_t) &= \mathcal{N}(\mathbf{z}_t; \mathbf{C}_t\mathbf{x}_t + \mathbf{d}_t, \Sigma_z) \\p(\mathbf{x}_t) &= p(\mathbf{x}_{t|t-1}) \\&= \mathcal{N}(\mathbf{x}_{t|t-1}; \mu_{t|t-1}, \Sigma_{t|t-1})\end{aligned}$$

We want to compute the joint  $p(\mathbf{x}, \mathbf{z})$

$$p(\mathbf{z}_t, \mathbf{x}_t) =$$

# Chain Rule

We know

$$p(\mathbf{x}_a) = \mathcal{N}(\mathbf{x}_a; \mu_a, \Sigma_a).$$

$$p(\mathbf{x}_b | \mathbf{x}_a) = \mathcal{N}(\mathbf{x}_b; \mathbf{A}\mathbf{x}_a + \mathbf{c}, \Sigma_{b|a})$$

We want to compute

$$p(\mathbf{x}_a, \mathbf{x}_b) = \mathcal{N}(\mathbf{x}_{a,b}; \mu_{a,b}, \Sigma_{a,b})$$

The parameters are

$$\mu_{a,b} = \begin{pmatrix} \mu_a \\ \mu_b \end{pmatrix} = \begin{pmatrix} \mu_a \\ \mathbf{A}\mu_a + \mathbf{c} \end{pmatrix}$$

$$\Sigma_{a,b} = \begin{pmatrix} \Sigma_a & \Sigma_a \mathbf{A}^T \\ \mathbf{A}\Sigma_a & \Sigma_{b|a} + \mathbf{A}\Sigma_a \mathbf{A}^T \end{pmatrix}$$

# Update: Chain Rule

Given the following distributions

$$\begin{aligned}p(\mathbf{z}_t|\mathbf{x}_t) &= \mathcal{N}(\mathbf{z}_t; \mathbf{C}_t\mathbf{x}_t + \mathbf{d}_t, \Sigma_z) \\p(\mathbf{x}_t) &= p(\mathbf{x}_{t|t-1}) \\&= \mathcal{N}(\mathbf{x}_{t|t-1}; \mu_{t|t-1}, \Sigma_{t|t-1})\end{aligned}$$

We want to compute the joint  $p(\mathbf{x}, \mathbf{z})$

$$\begin{aligned}p(\mathbf{z}_t, \mathbf{x}_t) &= \mathcal{N}\left(\begin{pmatrix} \mu_{t|t-1} \\ \mu_z \end{pmatrix}; \begin{pmatrix} \Sigma_{t|t-1} & \Sigma_{t|t-1}\mathbf{C}_t^T \\ \mathbf{C}_t\Sigma_{t|t-1} & \Sigma_z + \mathbf{C}_t\Sigma_{t|t-1}\mathbf{C}_t^T \end{pmatrix}\right) \\ \mu_z &= \mathbf{C}_t\mu_{t|t-1} + \mathbf{d}_t\end{aligned}$$

# Update: Conditioning

## Conditioning

$$\begin{aligned} p(\mathbf{z}_t, \mathbf{x}_t) &= \mathcal{N} \left( \begin{pmatrix} \mu_{t|t-1} \\ \mu_z \end{pmatrix}; \begin{pmatrix} \Sigma_{t|t-1} & \Sigma_{t|t-1} \mathbf{C}_t^T \\ \mathbf{C}_t \Sigma_{t|t-1} & \Sigma_z + \mathbf{C}_t \Sigma_{t|t-1} \mathbf{C}_t^T \end{pmatrix} \right) \\ \mu_z &= \mathbf{C}_t \mu_{t|t-1} + \mathbf{d}_t \end{aligned}$$

$$p(\mathbf{x}_{t|t} | \mathbf{z}_t) = \mathcal{N}(\mathbf{x}_{t|t}; \mu_{t|t}, \Sigma_{t|t})$$

# Conditioning

Let  $\mathbf{x}^T = (\mathbf{x}_a^T \ \mathbf{x}_b^T)$  be a Gaussian random variable such that  $\mathbf{x} \sim \mathcal{N}(\mathbf{x}; \mu, \Sigma)$  .

The conditional

$$p(\mathbf{x}_a \mid \mathbf{x}_b) = \frac{p(\mathbf{x}_a, \mathbf{x}_b)}{\int_{\mathbf{x}_a} p(\mathbf{x}_a, \mathbf{x}_b) d\mathbf{x}_a}$$

is Gaussian with parameters

$$p(\mathbf{x}_a) = \mathcal{N}(\mathbf{x}_a; \mu_{a|b}, \Sigma_{a|b})$$

$$\mu_{a|b} = \mu_a + \Sigma_{ab} \Sigma_{bb}^{-1} (\mathbf{x}_b - \mu_b)$$

$$\Sigma_{a|b} = \Sigma_{aa} - \Sigma_{ab} \Sigma_{bb}^{-1} \Sigma_{ba}$$

# Update: Conditioning

Given the joint, we want to condition on the current measurement

$$p(\mathbf{z}_t, \mathbf{x}_t) = \mathcal{N} \left( \begin{pmatrix} \mu_{t|t-1} \\ \mu_z \end{pmatrix}; \begin{pmatrix} \Sigma_{t|t-1} & \Sigma_{t|t-1} \mathbf{C}_t^T \\ \mathbf{C}_t \Sigma_{t|t-1} & \Sigma_z + \mathbf{C}_t \Sigma_{t|t-1} \mathbf{C}_t^T \end{pmatrix} \right)$$
$$\mu_z = \mathbf{C}_t \mu_{t|t-1} + \mathbf{d}_t$$

$$p(\mathbf{x}_{t|t} | \mathbf{z}_t) = \mathcal{N}(\mathbf{x}_{t|t}; \mu_{t|t}, \Sigma_{t|t})$$
$$\mu_{t|t} = \mu_{t|t-1} + \underbrace{\Sigma_{t|t-1} \mathbf{C}_t^T (\Sigma_z + \mathbf{C}_t \Sigma_{t|t-1} \mathbf{C}_t^T)^{-1}}_{\mathbf{K}_t} (\mathbf{z}_t - \mu_z)$$
$$\Sigma_{t|t} = \Sigma_{t|t-1} - \Sigma_{t|t-1} \mathbf{C}_t^T (\Sigma_z + \mathbf{C}_t \Sigma_{t|t-1} \mathbf{C}_t^T)^{-1} \mathbf{C}_t \Sigma_{t|t-1}$$

# Wrapup (Kalman Filter)

Predict: incorporate new control

$$\mu_{t|t-1} = \mathbf{A}_t \mu_{t-1|t-1} + \mathbf{B}_t \mathbf{u}_{t-1} + \mathbf{c}_{t-1}$$

$$\Sigma_{t|t-1} = \mathbf{A}_t \Sigma_{t-1|t-1} \mathbf{A}_t^T + \mathbf{B}_t \Sigma_u \mathbf{B}_t^T$$

Update: incorporate new measurement

$$\mu_z = \mathbf{C}_t \mu_{t|t-1} + \mathbf{d}_t$$

$$\mathbf{K}_t = \Sigma_{t|t-1} \mathbf{C}_t^T (\Sigma_z + \mathbf{C}_t \Sigma_{t|t-1} \mathbf{C}_t^T)^{-1}$$

$$\mu_{t|t} = \mu_{t|t-1} + \mathbf{K}_t (\mathbf{z}_t - \mu_z)$$

$$\Sigma_{t|t} = (\mathbf{I} - \mathbf{K}_t \mathbf{C}_t) \Sigma_{t|t-1}$$

# Non Linear Systems

If the system is non-linear, we can still use a variant of the Kalman Filter by dynamically linearizing the system at each time

This is known as the Extended Kalman Filter (EKF)

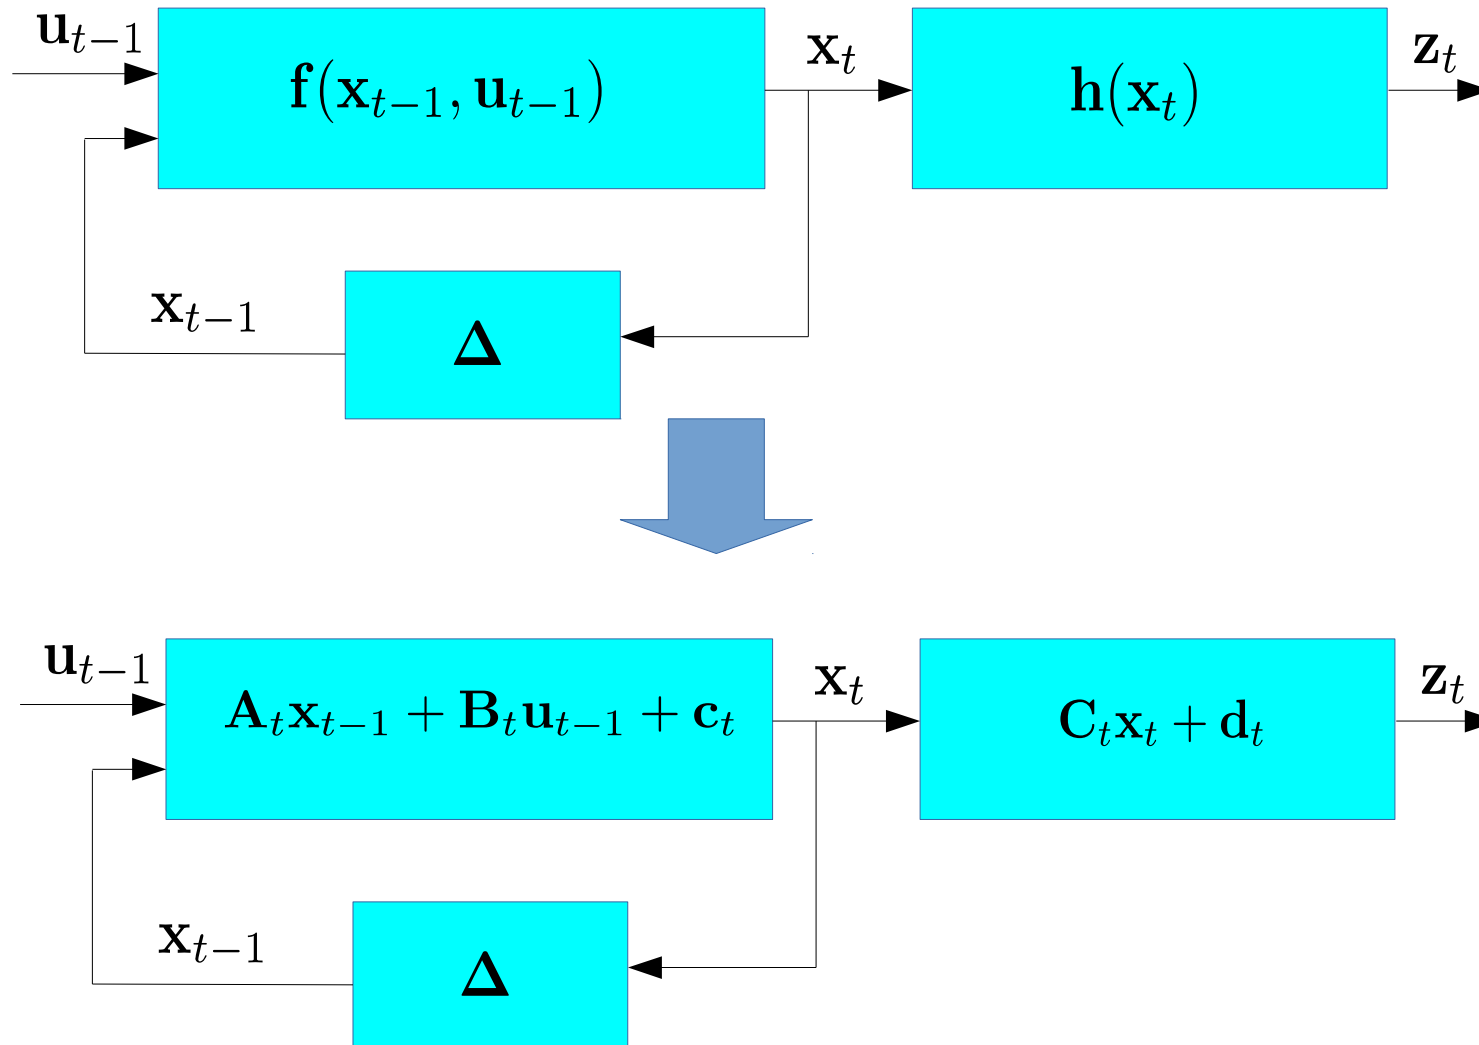

In contrast to the Kalman Filter, the EKF is not optimal, however

- for “smooth” transition and observation models
- small uncertainties

it is shown to provide good results.

# Linearizing a System

We want to construct a locally linear approximation of this model

# Taylor Expansion

Linearize the functions around the current state and measurement, at each iteration

Derivatives are computed around the current mean of the estimate

$$\begin{aligned} \mathbf{f}(\mathbf{x}, \mathbf{u}) &\simeq \mathbf{f}(\mathbf{x}_0, \mathbf{u}_0) + \underbrace{\frac{\partial \mathbf{f}(\mathbf{x}, \mathbf{u})}{\partial \mathbf{x}}}_{\mathbf{A}} (\mathbf{x} - \mathbf{x}_0) + \underbrace{\frac{\partial \mathbf{f}(\mathbf{x}, \mathbf{u})}{\partial \mathbf{u}}}_{\mathbf{B}} (\mathbf{u} - \mathbf{u}_0) \\ &= \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u} + \underbrace{\mathbf{f}(\mathbf{x}_0, \mathbf{u}_0) - \mathbf{A}\mathbf{x}_0 - \mathbf{B}\mathbf{u}_0}_{\mathbf{c}} \end{aligned}$$

$$\begin{aligned} \mathbf{h}(\mathbf{x}) &\simeq \mathbf{h}(\mathbf{x}_0) + \underbrace{\frac{\partial \mathbf{h}(\mathbf{x})}{\partial \mathbf{x}}}_{\mathbf{C}} (\mathbf{x} - \mathbf{x}_0) \\ &= \mathbf{C}\mathbf{x} + \underbrace{\mathbf{h}(\mathbf{x}_0) - \mathbf{C}\mathbf{x}_0}_{\mathbf{d}} \end{aligned}$$

# Wrapup (EKF)

Predict: incorporate new control

$$\mu_{t|t-1} = \mathbf{f}(\mu_{t-1|t-1}, \mathbf{u}_{t-1})$$

$$\mathbf{A}_t = \left. \frac{\partial \mathbf{f}(\mathbf{x}, \mathbf{u})}{\partial \mathbf{x}} \right|_{\mathbf{x}=\mu_{t-1|t-1}}$$

$$\mathbf{B}_t = \left. \frac{\partial \mathbf{f}(\mathbf{x}, \mathbf{u})}{\partial \mathbf{u}} \right|_{\mathbf{u}=\mathbf{u}_{t-1}}$$

$$\Sigma_{t|t-1} = \mathbf{A}_t \Sigma_{t-1|t-1} \mathbf{A}_t^T + \mathbf{B}_t \Sigma_u \mathbf{B}_t^T$$

Update: incorporate new measurement

$$\mu_z = \mathbf{h}(\mu_{t|t-1})$$

$$\mathbf{C}_t = \left. \frac{\partial \mathbf{h}(\mathbf{x})}{\partial \mathbf{x}} \right|_{\mathbf{x}=\mu_{t|t-1}}$$

$$\mathbf{K}_t = \Sigma_{t|t-1} \mathbf{C}_t^T (\Sigma_z + \mathbf{C}_t \Sigma_{t|t-1} \mathbf{C}_t^T)^{-1}$$

$$\mu_{t|t} = \mu_{t|t-1} + \mathbf{K}_t (\mathbf{z}_t - \mu_z)$$

$$\Sigma_{t|t} = (\mathbf{I} - \mathbf{K}_t \mathbf{C}_t) \Sigma_{t|t-1}$$

# Summary

- The Kalman Filter is an optimal observer of the state for linear systems under Gaussian noise
- It is a Bayesian Filter, that operates in a closed Gaussian world by estimating the parameters of the state distribution as new measurements and controls become available
- For non-linear systems we can still use the Extended Kalman Filter, but we lose optimality
- Widely used
